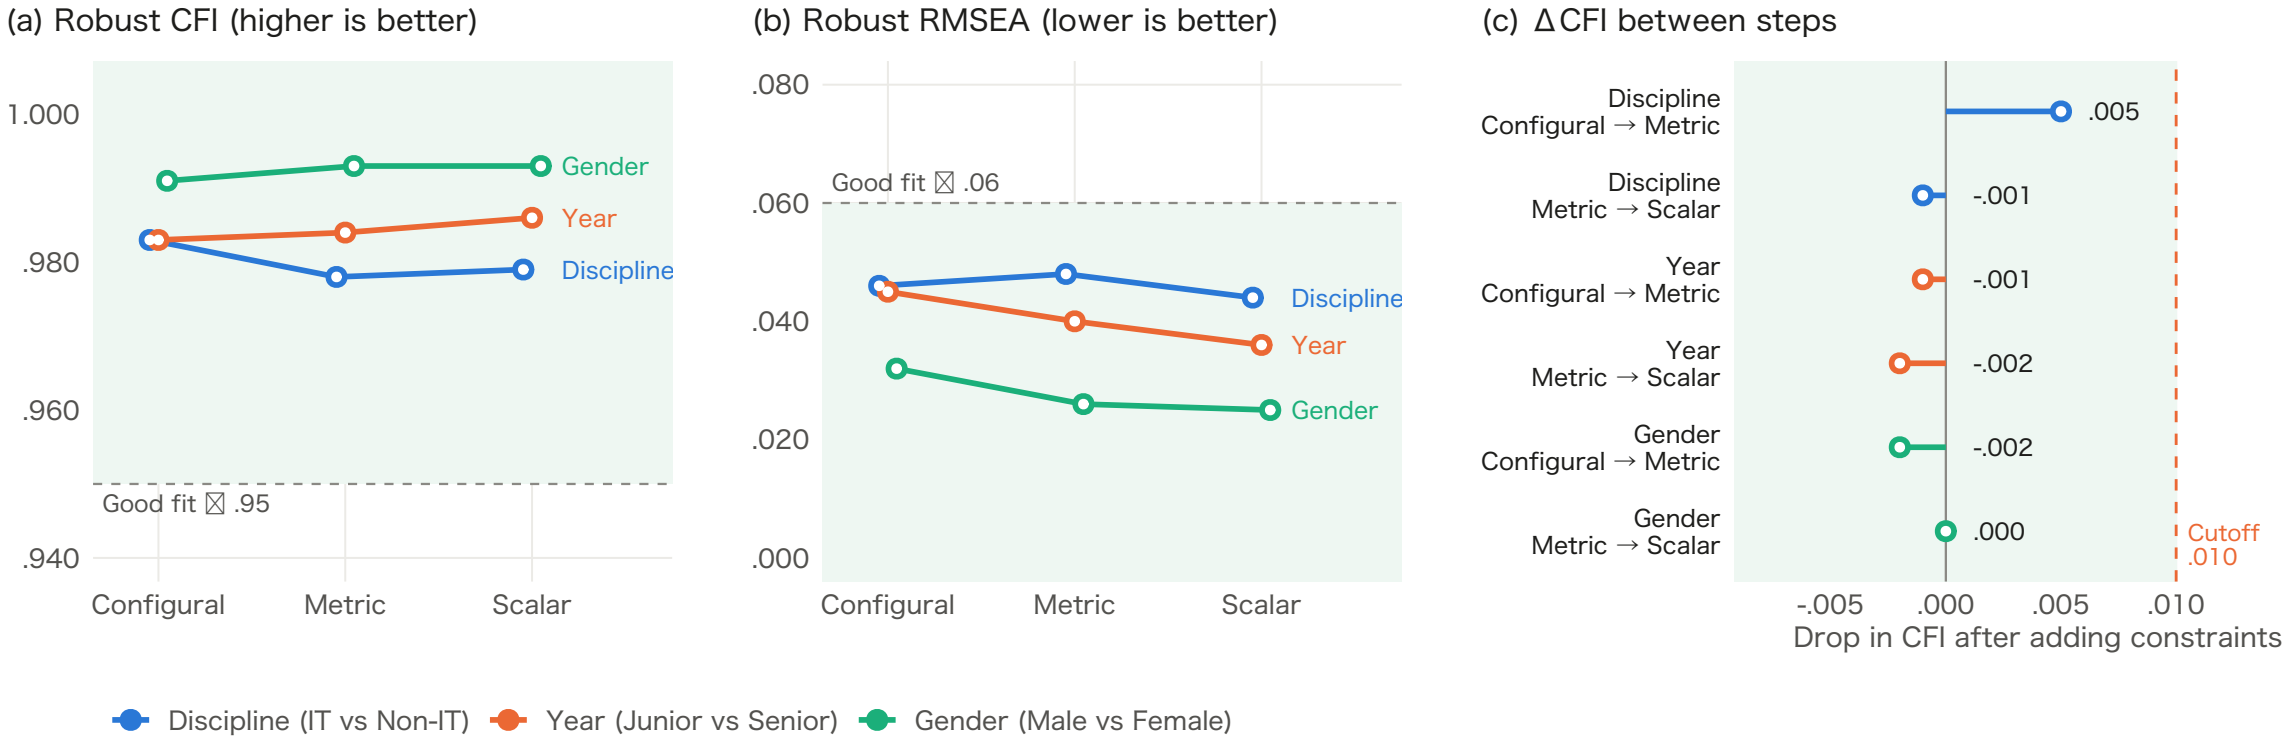
Measurement invariance of the AI career anxiety scale across student groups

Fit stays good as loadings (metric) and then intercepts (scalar) are held equal, and no constraint lowers CFI by more than .010.
The scale therefore measures the same construct on the same metric in every group, so group means can be compared.



Note. Multi-group CFA with MLR on the 9-item one-factor model. Groups: Discipline = IT vs non-IT; Year = Years 1–2 vs Years 3+; Gender = male vs female (respondents reporting another gender or preferring not to say excluded). ΔCFI cutoff follows Chen (2007); negative values mean fit improved.
